San Diego, June 2013***

Concerns for Future Directions in Chemically Reacting Flows

Elaine Oran

Naval Research Laboratory

Four Decades of CFD:

Looking Backward and Moving Forward

The JRV Symposium

San Diego, June 2013

***To be able to use computers to learn about
and -- with luck -- even predict the behavior
of reacting flows, we need algorithms for:***

***Solving for the fluid dynamics -- CFD,
and ways to represent***

***Chemical transformations -- ODEs ?, other?
and the technology to combine these.***

***Antony, Bram, and Phil are among those who have
provided some of the basic underpinnings of
modern CFD.***

Reactive Flows

Flows with localized reactions and energy release

“... encompass a very broad range of phenomena, including flames, detonations, chemical lasers, the earth's atmosphere, the Sun, stars, supernovae,...

Despite the obvious physical differences among these flows, there is a striking similarity in the forms of the descriptive equations. Thus the considerations and procedures for constructing numerical models of these systems are also similar.”

***Now consider some reactive flows
at very different scales***

Galaxy NGC4536

Type Ia Supernova, 1981B

Released $\sim 10^{51}$ ergs in 2s

Some Reactive Flows of Current Interest

Coronal Magnetic Eruption 2012

Wildfires ... Colorado 2012

Aircraft explosion 2008

Mine Explosion Greymouth, 2010

Flows are energetic, unsteady, high-speed, turbulent.

***Buncefield, UK
5 December
2005***

***Why was there
such extensive
damage?***

Rotating Detonation Wave Engine

Annulus perpendicular to an inlet and nozzle system. Incoming propellents are continuously ignited, and detonate, producing thrust. (Courtesy UT Arlington)

Scramjet Engine

Figure 1. The scramjet engine occupies the entire lower surface of the vehicle body (a). As air passes through the forebody, internal inlet, isolator, combustor, internal nozzle, and aftbody (b), it experiences a complex series of shock waves that change with speed and have to be carefully managed and integrated with the power design.

Atmospheric Reentry Flow

Summary of Concerns

For fast and variable flow with intense energy release ...

We don't know if the fluid equations hold.

We know the chemical mechanisms are wrong.

(And this says nothing about the other terms.)

Lament:

***“So it seems to me that the underpinnings are ... weak, weakening?
I had thought that reacting flows were on fairly solid ground. There
are some rumbles now, which could turn into earthquakes.”***

Reply:

***“I don't think they are weakening, I think they were never strong.
It may be that some people are realizing for the first time how weak
the underpinnings are. I hope this does not lead people to jump in off
the deep end. ‘Petit a petit l'oiseau fait son nid.’ Slow and steady is
what we want.”***

Intermittency

“Occurring at irregular intervals; not continuous or steady”

There are several meanings of “intermittency” in turbulence.

First, consider one of them, “the tendency of the probability distributions of some quantities in 3D turbulence (i.e., gradients or velocity differences) to develop extreme tails at the wings.”

Pdfs of longitudinal velocity gradient for several values of Re , increasing in direction of the arrow. Normalized by the standard deviation. Symbols are Gaussian.

*(Jimenez et al., 1993; Belin et al., 1997; Antonia and Pearson, 1999)
(Re in range 260 - 3.5×10^6)*

*** These tails become stronger as the Re increases. (This means that fluctuation level increases.) The effect does not show any sign of stopping at the highest Re 's .**

Intermittency in Turbulent Reacting Flows

How do variations in turbulent intensity (I_T) affect fluctuations of flow variables?

Turbulent flows and flow variables show intermittency, here quantified (by pdfs) as deviations from Gaussianity.

Enstrophy (vorticity Ω)

Scalar Dissipation (χ , i.e., $\text{grad } Y$)

(Key: $Y = 1$, blue, unreacted $Y = 0$, red, reacted
Log-normal models in the inset.)

What does intermittency mean for us practically?

Fluctuations in physical variables (P , T , v , ...) can have dramatic effects in an exothermic material.

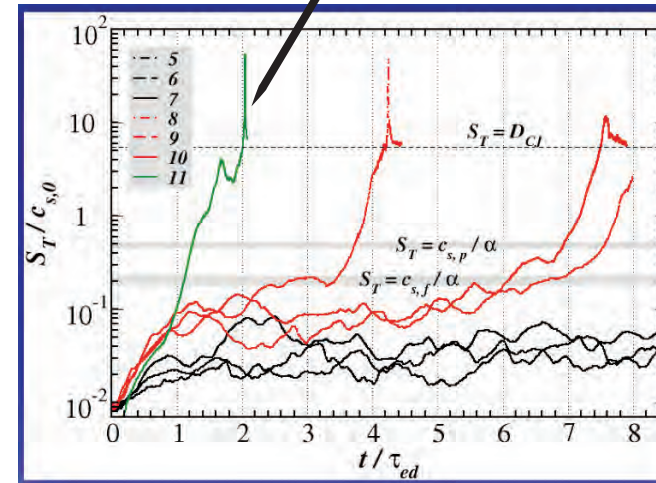

Fuel Mass Fraction

Pressure

Methane

One thing we know: there is more chance of an extreme event, a large and strong effect in the flow, to occur as Re increases.

Reasons for Worrying about Intermittency

Intermittency can affect the likelihood of extinction, re- and auto-ignition, DDT, instantaneously broaden or thin flames, and produce other extreme configurations

Intermittency strongly varies both with turbulent intensity and fuel mass fraction (position in the flame)

Turbulence (enstrophy, energy dissipation) is more intermittent for small intensities, particularly near products

Scalar dissipation is more intermittent for high intensities, especially near reactants

Intermittency increases with Re , T ,

Issues with Standard Chemical Reaction Mechanisms

**Complex hydrocarbons (e.g., biofuels, JP's, gasoline, ...):
Chemical reaction mechanisms with $\sim 10^4$ chemical
reactions are common. Mechanisms with $\sim 10^5$ and even
more reactions now proposed.**

Assumptions:

Equilibrium kinetics mechanisms.

Specific reactions intermediates.

Sequential steps represented by Arrhenius rates.

Rates and other input are guesses, extrapolations, fits.

Many unknown parameters.

**None of the proposed mechanisms (even hydrogen alone)
consider high-T,P conditions, or the presence of shocks.**

**Shocks put molecules into nonequilibrium excited states,
and these can be the states undergoing reactions.**

**Civil Asides: (1) At any location in space and time, very few of
these Arrhenius reactions and species are important.**

**(2) In the course of the reaction, excited states of short-lived
intermediates (known and unknown) can be critical.**

Test of a Chemical Reaction Mechanism

When combined with a fluid model, does it reproduce the “cleanest” measurements we can make?

- * Laminar flame speeds***
- * Flame instabilities***
(e.g., multidimensional cellular structure)
- * Detonation velocities (and variation on mean)***

**** Multidimensional detonation structure
(structure & size)***

This is where the algorithms that Jay, Bram, Phil and Antony have allowed us to compute accurately enough to be quantitative.

This is where the chemical models fail badly, both qualitatively and quantitatively.

Detonation Cells as a Test of Chemical Kinetics for High-Temperatures, High-Pressures

Early computations of cellular detonation structure using detailed chemical reaction models: e.g.,

Oran, Weber, et al. ~1998: 2D simulations of structure of detonation cells for low-pressure H₂-O₂, with Ar (~70%).

Detonation cell

Computed and measured cell sizes were similar (within factor of 2).

Repeated more recently by *Eckett (2001), Hu et al. (2004), and Dieterding (2011)*, with more resolution, updated chemical models, etc. *Computed and measured cell sizes still similar.*

Conclusion: For low-pressure, strong dilution (Ar, N₂), computed cell sizes are generally within a factor of 2 of measured cell size. Structure looks OK.

Most Recent Detonation Cell Computations:

H₂-air, 1 atm, 298K (*Taylor et al., 2011-12*)

**1-step, 12-step, 24-step, GRI-Mech, UCSD, ...
models, all fairly “standard” chemical models.**

4 different high-resolution numerical fluid dynamics methods.

***Result: All mechanisms, with any numerical method, give
computed cell sizes ~0.01 m, i.e., ~5-10 too small.***

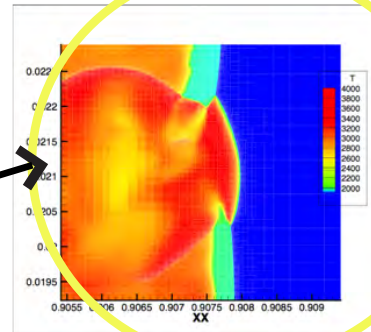

***(Burke et al. high-pressure chemical model gives
cell sizes ~4-5 times too small.)***

Computed cell structure (i.e., regularity, shape) is also wrong!

Why???

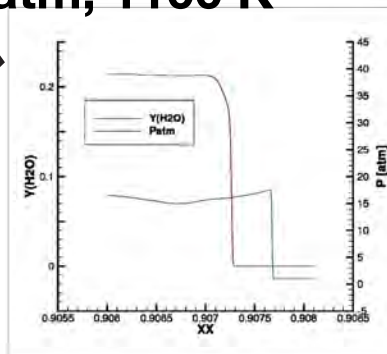

***This same trend for computed cell sizes is echoed
in measurements and simulations of detonation
cells for CH₄-air, 1 atm, 298 K (*Kessler et al.*).***

Reactive Flows under Extreme Conditions

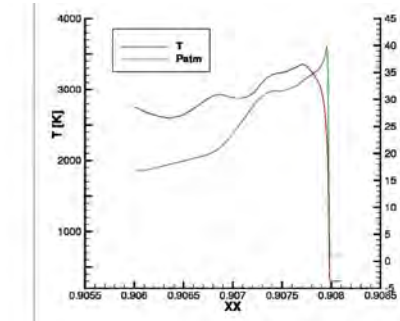

*Propagating detonation in
H₂-Air, 1 atm, 298K.
Burke et al. chemistry.
Computations by
Taylor, Kessler et al.,
2011-12 (Proc.Comb.Inst).*

Post-Shock State: 18 atm, 1100 K

Post-Shock State: 40 atm, 2200 K

Summary of Concerns

For fast and variable flow with intense energy release ...

We don't know if the fluid equations hold.

We know the chemical mechanisms are wrong.

(And this says nothing about the other terms.)

Lament:

***“So it seems to me that the underpinnings are ... weak, weakening?
I had thought that reacting flows were on fairly solid ground. There
are some rumbles now, which could turn into earthquakes.”***

Reply:

***“I don't think they are weakening, I think they were never strong.
It may be that some people are realizing for the first time how weak
the underpinnings are. I hope this does not lead people to jump in off
the deep end. ‘Petit a petit l'oiseau fait son nid.’ Slow and steady is
what we want.”***

Thank you for your kind attention !
